

Effects of Materials on Pregnant Women and Children

In most cases the appearance of diseases comes not from a genetic predisposition but from a cellular and genetic dependency on the influence of incoming negative frequencies.

For example:

A pregnant woman comes under the sphere of negative frequency influence from clothing, footwear, bedding, dental materials, etc. The unborn child's developing cells subconsciously receive constant polluting toxic frequency information in its memory.

As this information is accepted and memorized, the influences on the biochemical exchange processes in the body will be accepted and confused by the cell's toxic frequencies and will be compromised. Because of that, the original blueprint memory in the cells will be confused and in the future will not be able to correctly recognize the difference between healthy and toxic frequencies.

In the overwhelming majority of materials, the characteristic signals contain the frequency and wave structures of different diseases, disrupting the normal process of development in the child. In spite of the strongly developed shielding functions of the immune system, the development is suppressed and cells change in the process of pregnancy.

Since the fetus is not completely formed and is going through development of cellular learning processes, it is weak, and easily yields to physical changes. It accepts incorrect information, and in the development process, memorizes and gets attracted to wave structures of familiar negative frequency or diseases. This information is received and memorized as an incorrect blue print.

This incorrect information often dictates a subconscious choice of the selection of energetically familiar products having a toxic frequency. This creates not a genetic predisposition towards disease, but just the wrong memorized frequency attraction and challenges at the cellular level.

The individual makes the selection and purchase of goods, which are familiar to its previous sensations. The negative influence of the material's frequency contrasts to the state of a healthy body. The body and also the brain of the child are distracted in a fight with the negative electromagnetic influence coming from the materials. Brain activity, thoughts, reactions etc., which are just formed expressions of different electrical matters, become interrupted by negative electromagnetic frequency influences from different materials. The brain will have considerably more difficulty in receiving, understanding and memorizing correct information. This creates a trauma in the brain cells.

Chronic exposure to toxic frequencies causes metabolic changes by changing the nutrients around the cells in the brain, and results as degradation over time. The brain cells start to function in a more suppressed regime and cannot wash out and clean themselves. After this, the response analytical associative sections become blocked, poisoned and eventually destroyed by interruptions of incoming negative frequencies, which destroy and erase the original blueprint of intellect in cellular ability to recognize, accept and correctly process the incoming information of body functions. After that the blocked and poisoned brain begins to lose intellect and gradually and eventually turns off. This can be associated with a cognitive decline and the appearance of ADD, autism, Alzheimer's and other neurodegenerative diseases.
